Concussion Management Guidelines for Certified Athletic Therapists in Quebec

Corporation des Thérapeutes du Sport du Québec

Quebec Corporation of Athletic Therapists

© 2014
Acknowledgements

The Corporation des Thérapeutes du Sport du Québec (CTSQ) would like to acknowledge the Ad Hoc Concussion Standards Committee established in 2013, who dedicated themselves to the creation of this document and emphasized the importance of proper management of concussions. Extensive research and review of current internationally recognized concussion management standards and literature, enabled the committee to develop recommended guidelines for the safe and effective assessment and treatment of concussions by Athletic Therapists within Quebec.

The CTSQ wishes to acknowledge and thank the authors who worked tirelessly in creating and delivering this document. In alphabetical order, the authors are:

Laurie-Ann C. Berrigan, MSc, CAT(C)
John Boulay, B.Sc., EMT, DO, CAT(C)
Philippe Fait, PhD, ATC, CAT(C)
Laura Leslie, B.Sc., DO, CAT(C)
Jennifer Ann Scott, B.Sc., CSCS, CAT(C)

The authors created this document with help from the athletic therapy community by means of inspiration, guidance and support. The authors, as well as the CTSQ wish to express appreciation to everyone who contributed throughout the creation and editing of these guidelines.

This document will be reviewed and revised on an annual basis in order to remain current. The CTSQ will have all of the links within this document on their webpage available for download.

Introduction

Background

In the fall of 2013 the Corporation des Thérapeutes du Sport du Québec (CTSQ) mandated an ad hoc committee on concussion standards to provide a document describing the current standards for concussion and head trauma management. The goal was to ensure that Athletic Therapists (ATs) continue to provide the highest standard of care for their patients through the provision of a unified standard of response to concussions.

The overreaching desire of the CTSQ and this committee is to prevent possible patient mismanagement, unnecessary suffering, and inspire a positive effect on both the injured individual, and their support network.

A thorough research, review, and clarification of current internationally recognized concussion management standards and guidelines found in peer-reviewed sports medicine scientific literature was undertaken. The resultant document is a thorough representation of concussion management standards as they currently exist, and should serve as the standard of care for all Athletic Therapists (ATs) practicing in the province of Quebec. The document may also serve as a guideline for other healthcare professionals or persons who provide care to individuals who have sustained a concussion. These guidelines are appropriate for the treatment of children, young adults and adults. The document will be reviewed and revised on an ongoing and regular basis in order to remain current.

The Athletic Therapists Scope of Practice

Certified Athletic Therapists are front line health care professionals. As per the Quebec government decree, effective May 30th 2012: “Athletic Therapists are skilled in emergency response, clinical assessment and rehabilitation as well as return to play of any and all musculoskeletal injuries”.  

This statement illustrates that Athletic Therapists (ATs) in accordance with the highest standard of care are trained and prepared to provide the emergency assessment, treatment, ongoing monitoring, and return to play decision making associated with a concussion or mild traumatic brain injury (mTBI) while following age appropriate guidelines. As such, they are well suited to provide post-concussive care to athletes at the recreational, elite and professional level. They can also provide acute care services and facilitate active rehabilitation for an athlete’s safe return to play.
Athletic Therapists (ATs) are prepared to manage an athlete with a suspected concussion/mTBI at either a sports venue or as a patient in a clinical setting/training room. It is essential that these first encounters be dealt with expeditiously with methods based on the highest standard of healthcare.

**Concussion Interpretation**

It should be understood that the terms concussion and mTBI are interchangeable. In sports and everyday life, the term concussion is widely used and accepted as being a minor injury relative to a Traumatic Brain Injury (TBI). Whereas, a concussion is in fact a mild traumatic brain injury, it is important that it be understood as such. It is important that ATs, athletes, patients, and their support network understand the significance of the word “concussion”. This interpretation should raise awareness and increase caution and compliancy during the treatment and rehabilitation process required after injury.

While the long-term effects of concussion mismanagement are unknown, it is clear that the short-term mismanagement following a concussion leads to an increase in symptoms and delays in recovery.

There are different types of TBI that can occur and the terms diffuse and focal describe their characteristics. The diffuse type would refer to an injury where there has been a widespread disruption of neurological function caused by shearing of neuronal connections. Depending on the area of the brain that is affected, the injury can result in a wide range of deficits which can include and are not limited to changes in personality, loss of speech, inability to comprehend speech, motor impairment attention and/or memory deficits. The focal type refers to injuries that are more localized and potentially life threatening such as injuries with intracranial bleeding.

It is important to note than any direct or indirect head injury can also be associated to a traumatic brain injury of varying severity and as such a proper brain injury management assessment as per these guidelines should be performed.

**Consensus Model for Concussion Management**

Every 4 years, world leading experts publish a consensus statement on concussions in sports, as a result of the International Conference on concussion in sports, which the 4th edition took place in Zurich, 2012.

This consensus statement provides details on modalities and emergency care when it comes to concussions. Various groups also provide guidelines when it comes to concussions, however the CTSQ recommends following the guidelines outlined from the International Conference on concussion in sport, which reflect up-to-date research findings.
Due to the complexity of concussions, nature of the injury, current literature and many other factors evolving around this particular condition; such as age, maturation, medical history, and much more, the CTSQ advocates the use of a conservative approach. Each case must therefore be evaluated individually and the management strategy should take into account all factors.
Glossary

**Active rest:** A term used during the return-to-play (RTP) guidelines meaning that the person is still not permitted to participate in the return-to-learn (R2L) protocol and/or the RTP protocol, however the person is permitted to participate in activities of daily living that do not produce or exacerbate any concussion symptoms.

**Acute:** In the field, an injury is considered to be in the acute phase from the moment of injury until seventy two (72) hours post injury. In a clinical setting, during the treatment and recovery, the acute phase is up until 7 to 10 days post injury.

**Age category:** with respect to the currently available tools within these guidelines

- **Child:** As per the Quebec law; any person under the age of 18.
- **Adolescent & Young adult:** Any person between ages 13-25, including 25, as per brain maturation for current standards and management procedure in the province of Quebec.
- **Adult:** Any person over the age of 25 years old. 8, 9

**Child SCAT3:** An evaluation tool for concussions specifically for children under 12 years of age. 10

**Complete rest:** The absence of any and all cognitive or physical activity or stimulation.

**Concussion:** See definition for Mild Traumatic Brain Injury (mTBI). 11

**Coup-Contrecoup, Whiplash:** A term used to describe an direct or indirect injury to the head/neck caused by a sudden, forceful head/neck movement followed by subsequent forceful head/neck movements in the opposite direction. These movements can occur in flexion/extension, side-bending and rotation.

**Diagnosis:** An act reserve for physicians to identify an injury or disease based on testing, signs and symptoms.

**Diffuse axonal injury:** Type of concussion where there is a widespread disruption of neurological function caused by shearing of neuronal connections. 4, 5, 6

**Focal:** The tissue damage resulting in injury is more localized and potentially life threatening. 4, 5, 6

**Glasgow Coma Scale (GCS):** A tool used to assess and quantify a person’s level of consciousness/responsiveness. 7

**Mechanism of Injury (MOI):** The events leading up to the injury, which caused the injury to occur.
Mild traumatic brain injury (mTBI): A mTBI is an acute brain injury resulting from direct or indirect mechanical energy to the head from external physical forces. Operational criteria for clinical identification include:

a. One or more of the following: confusion or disorientation, loss of consciousness for 30 minutes or less, post-traumatic amnesia for less than 24 hours, and/or other transient neurological abnormalities such as focal signs, seizure, and intracranial lesion not requiring surgery

b. Glasgow Coma Scale score of 13–15 after 30 minutes post-injury or later upon presentation for healthcare. These manifestations of mTBI must not be due to drugs, alcohol, medications, caused by other injuries or treatment for other injuries (e.g. systemic injuries, facial injuries or intubation), caused by other problems (e.g. psychological trauma, language barrier or coexisting medical conditions) or caused by penetrating craniocerebral injury.¹²

Rehabilitation: The process of healing from an injury or disease through various forms of therapy.

Return-to-Play (RTP): Stepwise guideline for gradual return to participation in a particular activity after a concussion.

Sport Concussion Assessment Tool 3 (SCAT3): A concussion evaluation tool for individuals 13 years of age and older.¹¹,¹²

Signs: Any objective evidence of disease or injury that is observed by the health practitioner that may or may not have been noticed by the patient.

Slow-to-recover: Any athlete or individual who has sustained a concussion who is still symptomatic for a minimum of four weeks (28 days) after the injury.¹³

Symptoms: A characteristic of a disease or injury that is experienced and described by the patient to the health practitioner and is not visible to the health practitioner.¹¹

Traumatic brain injury (TBI): A TBI is a non-degenerative non-congenital insult to the brain, resulting from direct or indirect mechanical energy to the head from external physical forces causing trauma and possibly leading to temporary or permanent impairment of cognitive, physical and psychosocial functions, with an associated altered state of consciousness. It includes the overall spectrum of all severities from concussion/mild to moderate to severe.¹¹,¹²
1. Concussion Assessment Guidelines

1.1 On Field Assessment

1.1.1. Suggested Evaluation Tools

(Please see the references section for e-links)

- SCAT3: 13 years old and over \(^{11}\) – Appendix 1
- Child SCAT3: 5-12 years old \(^{10}\) – Appendix 2
- Graded Symptom Checklist (GSC) \(^{11}\) – Appendix 3
- Cranial Nerve Assessment \(^{14,15}\) – Appendix 4
- Glasgow Coma Scale (GCS) \(^{11}\) – Appendix 5

Mechanism of Injury

1.1.2 Assessment Procedure

Use the SCAT3 as part of the screening tools to help determine “Recognize & Remove” concussion signs.

1) MOI
   a) Determination of the mechanism of injury (MOI) is important for establishing what potential structures may be involved. The two most common types of MOI are from a direct hit to anywhere on the head, or from a whiplash type motion. These are also known as coup and contrecoup injuries. The coup usually produces injury on the same side of the impact. Whereas the contrecoup injury is a result of the head continuing to move after a sudden stop in the movement of the body, usually producing injury on the opposite side. Either MOI can cause injury and concussion and there is no evidence indicating which type is worse or has different or more severe symptoms.

2) Spinal precautions in effect
   a) Manually stabilize head-neck

3) Perform Primary Survey to identify red flags for ambulance transport.
   a) Primary Survey
      i) Determine level of consciousness, airways, breathing and circulation
      ii) UABCd/CABd (U includes non-scored GCS)

4) Non-scored GCS is performed during determination of Unconscious portion of primary survey: (GCS refer to appendix 5)
   (1) Evaluate level of Consciousness
      a) Ask: What happened? (Do eyes open if they were closed? Do they respond verbally or move?)
      b) Say: Open your eyes. (Do they open their eyes? Move?)
(c) Ask: Where does it hurt? (Do they respond verbally?)
(d) Say: Move your fingers? (Do they move their fingers?)
   NOTE: If no response with first 2 questions, go to pain stimulation.
(e) Invoke Pain: Pinch triceps and/or nail bed (Do they open eyes?
   NOTE: If no response at all: Glasgow= 3/15

5) Initiate Emergency Response Plan (ERP) as required  

6) Deal with any first aid / emergency care issues

7) Determine chief complaint/MOI

8) Perform secondary survey to rule out life/limb threatening injuries as per MOI if known.
   a) Secondary Survey includes:
      i) SAMPLE, full body-scan, vitals, GCS baseline score
      ii) Determine if concussion signs present?
            impairment? (LOC, balance/motor coordination issues, disorientation, confusion, memory loss, blank vacant stare, visible
            facial injury?)
      iii) Cranial nerves easily assessed on field:
         (1) II. Optic - visual acuity
         (2) III. Oculomotor - pupil reaction
         (3) IV. Trochlear - eye movements
         (4) VII. Facial – smile, grimace

NOTE: If serious red flags present during primary/secondary survey, athlete should be immobilized and transported to hospital via ambulance. If serious injuries present, without red flags during the primary/secondary survey, activate the ERP.

**RED FLAGS INCLUDE:**

- Loss of consciousness
- Deterioration of neurological function
- Decreasing level of consciousness
- Decrease or irregularity of ventilatory rate
- Decrease or irregularity of pulse
- Unequal, dilated or unreactive pupils
- Signs and symptoms associated with spine, skull fracture or bleeding
- Mental status changes; lethargy, difficulty staying awake, confusion, agitation, etc.
- Seizure activity, initial lucid (asymptomatic) interval, then presentation of rapid progressing symptoms
NOTE: If the athlete is conscious, alert, and has no red flags indicating serious head injury or need for spinal immobilization, the athlete can make their own way off the field, then the concussion assessment may continue on sideline.

1.2 Sideline Assessment

For field care situations, the evaluation may be continued on the sideline where the athlete is constantly monitored and re-assessed (serial assessment) for changes every 5 minutes. Ideally a quiet room would be the best setting, but not always realistic.

**IMPORTANT**
The athlete should not be left alone during the initial four (4) hours post injury.

The initial sideline assessment always focuses on trying to rule out a more serious injury in a timely fashion within the midst of competition. Once Glasgow score is scored, signs and symptoms of concussion are recorded. After monitoring and a rest period of at least 10 minutes, further SCAT testing is done which includes symptom severity, neurocognitive and physical evaluations.

**IMPORTANT**
The prior rest period is necessary to avoid influence of exertion or fatigue.

Thereafter, a sideline assessment is similar to a clinic visit, where it is safe to have been moved to complete a more thorough evaluation, or when an athlete presents him/herself to the Athletic Therapist (AT) during or after a game to seek help for head injury.

1.2.1 Evaluations tools for the sideline assessment

(All of these tools are available via their website in the reference.)

- SCAT3: 13 years old and over 11 – Appendix 1
- Child SCAT3: 5-12 years old 10 – Appendix 2
- Graded Symptom Checklist (GSC) 11 – Appendix 3
- Cranial Nerve Assessment 14, 15 – Appendix 4
- Glasgow Coma Scale (GCS) 11 – Appendix 5
  
  NOTE: repeat GCS every 5 minutes for first 15 minutes post trauma if score is 13-14/15
- Maddocks Score
- Background and Concussion history
NOTE: The following are to be done at resting state (at least 10 minutes post exercise)

- Symptom Evaluation
- Cognitive & Physical evaluation
- Neck Examination
- Balance Examination
- Coordination Examination
- Standardized Assessment of concussion (SAC)
- Delayed recall

NOTE: Regardless of assessment tool chosen, it should include the following criteria:

- History and observation/MOI
- Orientation (time – space) and memory
- Level of consciousness
- Signs and symptoms (see Table 1)
- Cognitive function
- Cranial nerve function (see Appendix 4
- Balance
- Coordination

1.2.2 Evaluation procedure

Document SCAT3 findings at time of injury and compare with baseline if available.

Complete GSC at time of injury, 2-3 hours, 24 hours, 48 hours, 72 hours post concussion.

**IMPORTANT**

Provide copies of both SCAT3 and GSC to the responsible adult doing home monitoring and for physician visit.

If EMS is called, transfer of care should involve giving the paramedics the original copy of completed SCAT3 and intervention notes. The AT can take a picture of the form with their camera for later reference and documentation.

In all cases, it is highly recommended that athletes with suspected head injury seek medical attention.

An athlete with suspected concussion can never RTP same day and must follow currently accepted age-specific RTP guidelines.

*Note: Concussion should be suspected in the presence of any or more of the above symptoms following some form of head injury.*

---

* Table 1 was taken directly from page 184 from Muriel Lezak’s book, Neuropsychological Assessment, which she adapted from SCAT2 and Halstead and Walter (2010).
1.3 Clinical Assessment

Regardless of the nature and complexity of the signs and symptoms associated with the head injury, ATs should always approach this condition in the same clinical manner that they would address any other musculoskeletal injury.

The clinical concussion assessment would include secondary complimentary subjective and objective history taking questions. Physical examination would include specific concussion related special tests to recognize certain concussion injury consequences and provide proper decision making processes for the treatment and / or the healthcare referral of the concussed athlete.

1.3.1 Components of a complete Clinical Assessment:

1.3.1.1 Balance Error Scoring System (BESS Balance Test)

   NOTE: Assessment of balance and postural control clinically is considered a reliable and valid assessment tool for concussed athletes / individuals 7, 19, 20

Procedure: Use modified BESS Balance Test
   a. Double leg stance (for 20 seconds)
   b. Single leg stance (for 20 seconds)
   c. Tandem Stance (for 20 seconds)

1.3.1.2 Vestibular/Vision Assessment

   a. Smooth Pursuits Test:
      - Tests ability to follow object smoothly without effort/strain or nystagmus
   b. Convergence Test:
      - Test ability to follow converging object without effort/strain or double vision 21, 22

1.3.1.3 Rivermead Post-Concussive Symptom Questionnaire (RPQ):

   a. A modified version of the original 23 RPQ that separates the scoring into two parts – RPQ-3 and RPQ-13. – Appendix 6

      NOTE: This modification demonstrates that the RPQ can be used clinically as a subjective test-retest assessment tool for concussion symptoms. 23

1.3.1.4 Physical Evaluation of the Cervical Spine:

   Assessment of the cervical spine should be performed as per CATA scope of practice guidelines for cervical spine evaluation. 14
1.3.1.5 SCAT3 / Child SCAT3

SCAT3 – For individuals aged 13 and older ¹¹ – Appendix 1
or
Child SCAT3 – For children from age 5-12 years old. ¹⁰ – Appendix 2

NOTE: With individuals aged 5-12 years old it is outlined that cognitive rest is an important factor of the concussion recovery. ¹⁰

1.3.2 Adjunct Testing

1.3.2.1 Physician directed tests

The following tests are physician directed, however still important for the Athletic Therapist to acknowledge within or in addition to their assessment:

NOTE: Computed Axial Tomography (CAT) and conventional Magnetic Resonance Imaging (MRI) usually fail to detect evidence of structural brain abnormalities in concussions. However, reviews of research in the biomechanical modeling of mTBI conclude that mTBI leads to functional neuronal disruption, and at times structural damage. ²⁴, ²⁵, ²⁶

1.3.2.2 Assessment performed by a neuropsychologist

Neuropsychological Assessment (NP) by a neuropsychologist allows the AT to assist clinical decisions relevant to the overall management of the concussed athlete, with addition to other management tools. Some NP testing tools can be used for both child and adult age populations.

NOTE: However, due to the continual cognitive development of the child during the maturation period, NP testing has been shown not to be as effective as a baseline test or a comparison model.
2. Concussion Treatment Guidelines

2.1 On field and Sideline Treatment

Concussions are one of the most difficult injuries to treat on-field or sideline. Each athlete may respond differently to head trauma and it is difficult to find one protocol that will be applicable in every case. Athletic Therapists (ATs) must make an informed decision on concussion management with the tools available and treat with utmost care.

Sometimes the presence of concussion signs makes it difficult to determine whether a more serious injury exists or will develop. The range of potential differentials may include, however is not limited to; an epidural bleed, subdural hematoma, intra-cranial contusion, and Second Impact Syndrome (SIS).

Recent studies are giving more credence to a more conservative approach to concussions. 27, 28 There is some emerging research evidence that vascular injuries can occur even in mild traumatic brain injuries. 29, 30

2.1.1 Evaluation Tools

a. SCAT3: 13 years old and over 11 – Appendix 1
b. Child SCAT3: 5-12 years old 10 – Appendix 2
c. Post-Concussion Symptom Inventory
   o Post-Concussion Symptom Inventory Child (PCSI-C) 31
     Ages 5-12 – Appendix 7
   or
   o Post-Concussion Symptom Inventory (PCSI) 31
     Ages 13-18 – Appendix 7
   or
   o Post-Concussion Symptom Inventory (PCSI-P) 31
     Parent of child aged 5-18 – Appendix 7
   or
   o Graded Symptom Checklist (GSC) 11
     Aged over 18 – Appendix 3

2.1.2 On-Field Management

• If a concussion is suspected, the athlete should be removed from play.
• Determine if there are indications for emergency management protocols (c-spine, seizure, etc.). If there are any doubts about urgency of symptoms, Emergency Response Plan (ERP) 16, 32 should be initiated, the athlete should be provided necessary care, closely monitored, and urgently referred to an ER physician by ambulance.
• Use age appropriate SCAT3 \(^{11}\) or Child-SCAT3 (5-12 years old) \(^{10}\) tool to determine possible presence of a concussion. \(^{33}\)
• If the athlete is not deemed to have a medical emergency or contraindications to transport off the field, the athlete may be moved to the sideline for further assessment. \(^{33}\)

2.2 Sideline Management

Further assessment in more detail may be carried out on the sideline to determine the extent of concussion.

• Appropriate care is provided as per presentation of symptoms.
• The athlete is continuously monitored especially the first 30 minutes until a plan of action is made.
• A physician referral plan is made: (see Referrals following a concussion section 2.4 \(^{34}\))

**IMPORTANT**
The athlete should not be left alone during the initial 4 hours post injury.

**NOTE:** Documentation of acute concussion signs will help with the return to play (RTP), especially if there is no baseline available. Comparison to a baseline may be used when available to detect subtle signs, which may be missed.

2.3 Global Management

Every athlete who has received a direct or indirect head trauma should be monitored from time of injury to a point where signs and symptoms have completely cleared.

All athletes with any signs/symptoms of an acute concussion are removed from play for minimum of 1 week for an adult \(^{7}\) or 2 weeks for a child, \(^{35}\) and must follow acceptable age-appropriate RTP guidelines. \(^{35}\)

**IMPORTANT**
Generally a graduated RTP should only proceed once an adult athlete has been asymptomatic for at least 24 hours. A child will need a longer period of rest, which ranges between 1-7 days before the graduated RTP protocol commences. \(^{36}\) Every case is different and is affected by co-morbidities and history.

**NOTE 1:** The determination of the safest initial rest period duration for athletes ≤ 25 years of age remains one of the biggest challenges due to the lack of consensus. Thus the recommendation from the CTSQ is to air on the side of caution and encourages a longer rest period for this age group.
NOTE: 2 The availability of baseline values is an important tool in the assessment and treatment of concussions. Every AT should strive whenever possible to have a database of baselines available for athletes under their care. Some symptoms can be present pre-morbidly or at baseline, so it would be valuable to note changes from their usual presentation.

**IMPORTANT**
The parent or legal guardian should fill out the Post-Concussion Symptom Inventory (PCSI) form for parents and help the athlete fill out the age appropriate PCSI form for children to allow for proper monitoring of the signs and symptoms of the concussion. This will also allow for adequate documentation of the athlete’s progress throughout the rehabilitation and return to play. See the Appendix 5 for instructions on how to fill out and use the PCIS.  

### 2.4 Referrals following a concussion

All concussions should be referred to a physician, ideally one who has experience dealing with head injuries for follow-up investigation. In some concussion cases, symptoms may take up to 72 hours to develop. Therefore, AT’s should remain in contact with their injured athlete and/or the person monitoring them for the first 48-72 hours to ensure appropriate follow-up is made.

A physician referral is also required if further diagnostic testing is indicated, medications prescribed, or if there are medical forms/letters that must be completed for school or work.

There are generally three categories of physician referrals:

- Urgent referral
- Same-day referral
- Post-concussion referral

#### 2.4.1 Urgent referral

Requires immediate referral to an ER physician by ambulance. The athlete would be immobilized and then transported urgently to the nearest trauma hospital.

It is prudent to be over-cautious, but there are realities of the pre-hospital care system that should be considered. The current 2013 protocols for the Services Préhospitaliers d’Urgences du Québec (Quebec Emergency Medical Services) indicate use of cervical collar and full spinal immobilization (including vacuum mattress) for ANY head injury. The use of urgent referral should be validated before use. However, if there is any doubt, initiate ERP including 911 ambulance dispatch sooner than later.
The following are typical red flags indicating need for an urgent referral:

- Unconsciousness / prolonged loss of consciousness
- Altered or decreasing level of consciousness
- Decreased neurological function
- Decreased or irregularity in pulse
- Unequal / dilated / unreactive pupils
- Mental status changes such as lethargy, non-arousal, confusion, agitation
- Seizure activity, lucid interval
- Convulsions
- Vomiting
- Severe or increasing headache
- Visual changes
- Slurred speech
- Any sign / symptoms of associated injuries such as to the spine, possible skull fracture or cranial bleeding.

**IMPORTANT**

When Emergency Medical Services (EMS) is called, transfer of care should involve giving the paramedics a copy of completed SCAT3 and intervention notes. Having a means to make a quick copy for later reference / documentation is useful, such as a camera phone.

### 2.4.2 Same Day Referral

A physician’s office visit is recommended on the same day for concussion follow-up when there are no urgent red flags present. The AT would not leave the athlete for at least 30 minutes. The athlete would be monitored by either an AT or delegated to a responsible adult/guardian for any deterioration until seen that day. If a same day office/clinic visit is not possible for any reason, it is recommended that the athlete be taken to the ER, however an ambulance should not usually be required.

Same day referral criteria includes:

- No loss of consciousness
- Alert, oriented, normal neurological exam
- Minimal symptoms that persist more than 15 minutes
  - mild nausea
  - mild light/noise sensitivity
  - mild memory issues
  - any alteration from baseline (if available)
- Headache still present after 15 minutes
  - The pain is constant
• does not increase in intensity
• is not severe
• No other urgent indicators

**IMPORTANT**

The athlete should be monitored for the next four hours before a decision to refer as a same-day or post-concussion referral is made.

It is important to provide the person monitoring the athlete a completed copy of SCAT3 that also includes concussion injury advice. Also give them a copy of GSC form (within initial findings) for home monitoring.

**RECOMMENDATION:** A physician note should also be obtained stipulating whether a follow-up physician visit is required before RTP can be done under guidance of an AT.

### 2.4.3 Post-Concussion Referral

A physician’s office visit is recommended within the next few days for concussion follow-up in absence of urgent or same day referral criteria. The consultation with the physician would be within the next 3 to 7 days.

This visit will ensure medical follow-up, documentation of condition, completion of forms for insurance or medical notes for absences and/or academic accommodations.

Post-Concussion referral criteria includes:
- Mild headache (as listed under same day criteria) with absence of red flags
- All other symptoms completely gone within 15 minutes

**IMPORTANT**

The athlete would not leave the presence of the AT for at least 30 minutes and the athlete would be monitored for any deterioration until seen by physician.

It is important to provide the person monitoring the athlete a completed copy of SCAT3 which also includes concussion injury advice along with a copy of GSC form (within initial findings) for home monitoring.

**RECOMMENDATION:** A physician note should also be obtained stipulating whether a follow-up physician visit is required before RTP, or that the RTP can be done under guidance of an AT.

**NOTE 1:** In some cases, athletes with minimal initial symptoms will have been removed from play for precautionary reasons. When these symptoms resolved quickly, without issue and complication, follow a graded RTP (See below for RTP).
NOTE 2: It often happens that the athlete may never see a physician. This reality was voiced at a 2013 sport concussion seminar and may prove to be more the rule than the exception. The CTSQ will further address this issue and provide direction in future updates to this document.

2.5 Additional information

2.5.1 Return to Hospital / Worsening Symptoms

It should be understood that during an initial hospital ER visit, a CT scan may not always be done. If symptoms worsen or any red flags appear (usually within first 24-48 hours), the athlete should return to the same hospital. Physician discretion would dictate whether imaging would be of benefit in this situation. CT scans are used sparingly and only in urgent situations, especially in the pediatric population.

Although initially the injury seems mild and that there was no transportation to the hospital, the symptoms should be monitored closely as they may worsen with time.

Specific neurological indicators that show need for referral to emergency room include:

- Loss of consciousness
- New, Worsening or changing headache
- Severe Headache
- Persistent or increasing neck pain
- Repeated vomiting (adult >1 time, less than 13yrs old >3 times)
- Dizziness
- Double vision
- Difficulty recognizing people / places
- Weakness / numbness in limbs
- Increasing confusion or irritability
- Slurred speech
- Seizure
- Difficulty walking, difficulty with balance
- Excessive drowsiness.
- Personality changes
- Any symptom that concerns athlete or person caring for athlete.

2.5.2 Home Care and Monitoring

Careful monitoring the first 24-72 hours is critical to identify any evolving issue.

If the athlete does not need to see a physician same-day, the AT should provide a structured plan for home care and monitoring. This includes giving a copy of initial GSC and instructions. To ensure adequate home monitoring, GSC should be
completed at time of injury, 2-3hrs, 24hrs, 48hrs, and 72hrs post injury. The age-
appropriate PCSI forms, provided by the AT, should be completed by the parent
and child during the homecare and monitoring time frames.

Any change or deterioration in cognitive / physical state or symptom severity
requires an immediate physician evaluation.

The following is a list of criteria for immediate physician evaluation. 41

- Loss of consciousness
- New, Worsening or changing headache 17, 38
- Severe Headache
- Persistent or increasing neck pain
- Repeated vomiting (adult >1 time, less than 13yrs old >3 times) 38, 39
- Dizziness
- Double vision
- Difficulty recognizing people / places
- Weakness / numbness in limbs
- Increasing confusion or irritability
- Slurred speech
- Seizure
- Difficulty walking, difficulty with balance
- Excessive drowsiness.
- Personality changes
- Any symptom that concerns athlete or person caring for athlete.

**IMPORTANT**

As cognitive rest is important, the practice of keeping awake or waking up the
athlete the first night is not advised. 42, 43, 44, 45 This practice may in fact disrupt
sleep patterns, increase symptoms the next day due to combined effects of injury
and sleep deprivation. Sleep is restorative and the athlete should be allowed to
sleep. 46

However, the parent or designated guardian should check in on the athlete after
they are asleep. Suggested monitoring the first night may involve quickly observing
the athlete while they are sleeping to take note of abnormal breathing patterns,
excessive snoring, posturing, or distress. This can be done 2 and 4 hours after the
athlete has gone to bed. At this point the parent/guardian can also note if the
athlete is not sleeping. If there is any doubt in athlete’s condition, the athlete should
be woken up to be sure they can be awakened, there is no amnesia or increase in
symptoms requiring an urgent intervention.

General rules in management usually involve waking the athlete up only if the
athlete had experienced a LOC, prolonged period of amnesia, or still experiencing
significant symptoms. 47
2.5.3 Athletic Therapist follow up

The completed GSC and PCSI forms should be brought to subsequent physician / AT visits. Ideally the AT should see the athlete on daily basis to monitor symptoms until they resolve and be directing the RTP. In the first day or two post-injury, a contact by phone may suffice to check on progress.
3. Clinical Treatment

3.1 Protocols

Clinical assessment should reveal treatment goals. Treatment should include the following components of a rehabilitation program and should ideally be interdisciplinary:

- **Soft Tissue Mobilization / Manual Therapy:**
  - To reduce tension in the musculoskeletal system that may be contributing to prolonged concussive symptoms (cervicogenic headache, dizziness, tinnitus, nausea, poor balance, auditory complaints, ear/eye pain). 7, 21, 49, 50

- **Cervical Spine Stability Exercises:**

- **Deep cervical flexor activation exercises** 7, 49, 50

- **Muscle Flexibility Exercises** 7, 49, 50

- **Postural Balance Exercises** 21, 49, 50

- **Core Stability Exercises** 7, 49, 50

- **Vestibular/Vision Exercises** 21, 49

Furthermore when providing concussion rehab guidelines, the following should be included:

- **Return to Play Guidelines** 7, 10, 11, 23, 49, 50

- **Sleep Hygiene education** 49, 50

- **Pharmacological management (physician directed)** 7, 49, 50

- **Psychological management (physician or neuropsychologist directed)** 7, 21, 49, 50

**IMPORTANT**

As stated earlier, any athlete who is still symptomatic and considered slow to recover (refer to glossary), should be re-refereed and re-evaluated by a physician. The athlete should also consult a health care professional who is an expert in the management of concussions. An interdisciplinary approach is recommended 48.

3.1.1 Importance of awareness and education

NOTE: Awareness of concussions and its effects are a very importance component of clinical concussion rehab.

Adult Population:

- Occupational concussion management education 21, 50
Child Population:
- Parent/family concussion management education 10, 50
- School/teacher concussion management education 10, 50
- Sport/coach concussion management education 10, 50

3.2 Special Considerations

3.2.1 Post-Traumatic Headache

Post-traumatic headache is the most common symptom of sport-related concussion. This is one of the symptoms that make it difficult to determine urgency of referral. The International Headache Society has a classification category for secondary headaches associated with head and neck trauma.

The four most common classification of post-traumatic headaches are: 51

I. Tension type (including cervicogenic component)
II. Migraine
III. Combined migraine and tension-type
IV. Cognitive fatigue

3.2.2 Medications

It is recommended that only physicians with experience in the management of concussions prescribe medication for this purpose. As long as the athlete is on medication, any return (RTP) should be considered with caution since medication may hide signs of an evolving issue.

3.2.3 Second Impact Syndrome (SIS)

Second Impact Syndrome is a rare occurrence, but can lead to catastrophic results or a further delay in recovery. Second Impact Syndrome can occur when an athlete is subjected to a second direct or indirect head injury while still experiencing symptoms from a prior injury. This seems to occur until late teens to early twenties. Care should be taken not to receive another insult to the brain while still experiencing signs of a concussion. 52, 53, 54
3.2.4 Vomiting

Vomiting after a head injury may have different implications depending on the situation. For children (<13 yrs old), persistent vomiting (>3 times) is a more reliable indicator. For adults more than once would be suspect in absence of migraine/motion sickness history. Some people with family or personal history of migraines or motion sickness may be more prone to vomiting after a head injury and may not be indicative of head injury severity. Persistent vomiting may be more of an indicator than a single occurrence post trauma. Approximately 10-15% of children vomit after a mild traumatic brain injury.

3.2.5 Summary Statement Regarding Physician Referrals

An athlete with suspected concussion can never RTP same day and must follow currently accepted age-specific RTP guidelines.

Any athlete who is still symptomatic and considered slow to recover (refer to glossary), should be referred and re-evaluated by a physician. The athlete should also consult a health care professional who is an expert in the management of concussions. An interdisciplinary approach is recommended (refer to clinical treatment guideline – clinical).
4. Comments regarding Pre Season Screening and Post Injury Evaluation

To date there is no agreement on the best screening tool due to the many factors that are involved such as means of administration cost, type of sport, population, etc. The following is a list of widely used, accepted and scientifically validated assessment tools to be used as reference.

Computerized Neuropsychological Assessment (NP) testing:

• Currently demonstrates variable test-retest reliability
• Greater reliability when testing the visual motor speed and reaction times
• Online version had fewer invalid baseline results versus the desktop version

SCAT3:

• Currently there is no scientific validation research on the SCAT3, despite that fact, it is still recommended within the Zurich 2012 Consensus statement.

SCAT2:

• There is not enough evidence to support the use of the total/composite score
• There is good evidence supporting the use of scoring of each component separately – revised SCAT2
• Baseline balance testing shows good evidence in both adults and child populations
• Baseline concentration testing in child athletes is unreliable producing numerous false positives and false negatives

Revised Rivermead Post-Concussive Symptom Scale:

• Only scale that is empirically driven
• Developed prior to clinical use
• A modified version of the original RPQ that separates the scoring into two parts – RPQ-3 and RPQ-13. This modification demonstrates that the RPQ can be used clinically as a subjective test-retest assessment tool for concussion symptoms.

McGill ACE Post-Concussion Symptoms Scale

• Used clinically to provide and evidence-based clinical protocol at the initial evaluation.
5. Return to Play Guidelines

Return to play (RTP) procedures after suffering a concussion follow a progressive stepwise manner based on symptoms experienced by athletes. RTP should be individualized, progressive, sport and age-specific and based on critical clinical judgment.

**IMPORTANT**
An athlete should never return to play or activities on the day of the injury, even if signs and symptoms have cleared.

In order to diminish, and eventually eliminate symptoms related to the concussion, physical and cognitive rest for a period varying between 24 hours for adults and up to seven days for children, is necessary. In the case of persistent symptoms, complete rest longer than seven days should be approached cautiously, instead, gradual exposure to physical and cognitive activities (if and only tolerated) for short periods of time can be of help in order to reduce symptoms before undergoing the stepwise approach to return to play.

**IMPORTANT**
It is crucial, however, that the stepwise approach to return to activities only be attempted when symptoms have fully resolved.

RTP should be monitored on a daily basis by the AT to monitor presence/absence of symptoms and suggest proper sport-specific and exercises as well as appropriate intensity.

5.1 Age considerations

Studies in the field of brain development and maturation suggest that the child’s brain continues evolving until early adulthood. Even though, the total brain size reach 95% of its maximum size by age six, its cortical and subcortical components change dramatically during childhood and adolescence. However, the full brain maturation is said to be achieved between the ages of 20 and 30 years, with the prefrontal cortex to be one of the last brain regions to mature. For these reasons, RTP procedures have been separated between two age groups, children and young adults less than 25 years of age, and adults over 25 years of age.

NOTE: The Quebec health system recognizes any individual under 18 years old to be a child. Hence, return to play procedures for children include a rest period of several days. For example, The Montreal Children’s Hospital recommends a seven-day rest period before entering RTP procedures. Due to age considerations for brain maturation between the ages of 18 and 25, we highly
encourage proper clinical judgment in the number of rest days to be prescribed and strongly recommend a longer rest period as opposed to a shorter one.

5.2 Return to Play for Children & Young Adults (≤25 years old)

To help with the return to play (RTP) process and to allow proper cognitive rest, it is highly encouraged that children modify their school attendance and activities in order to decrease symptoms. Hence, full return to school (meaning the child can tolerate a full day at school, with normal course load) is greatly advised before children can undergo the stepwise approach to return to sports/activities.
5.2.1 Return to Learn†

Best practice suggests that:

- Communicate with the school (school nurse, teacher, and/or school mental health professional) and sign a release of information for the school personnel to coordinate with the AT.
- The interdisciplinary team consisting of the AT and the school administrators decide together the level of academic adjustment needed at school depending upon the type and severity of the symptoms present and the times of day when the student feels better or worse.

**IMPORTANT**

The return to learn approach consists of 6 stages that should be separated by a minimum of 24 hours without symptoms before proceeding to the next step. Furthermore, throughout this process, there should be no physical activity.

Step 1
- Cognitive rest
  - no reading, no homework, no computer, no video games, no smartphone.

Step 2
- Gradual reintroduction of cognitive activity
  - Gradually integrate cognitive activities for short periods of time

Step 3
- Homework before school attendance
  - Able to perform homework
  - When the student is beginning to react well to 30 minutes of light mental activity, consider returning to school.

Step 4
- School re-entry
  - Part of day school attendance, homework

Step 5
- Reintegration into school
  - Increase to full day of school

Step 6
- Return to learn, full cognitive workload
  - Return to school, including tests and exams, catch-up work, etc

† Adapted from Importance of ‘return-to-learn’ in pediatric and adolescent concussion by Master, Gioia, Leddy & Grady. 65
5.2.2 Return to Play‡

Step 1
- No Activity
  - Requires that children and young adults be symptom free for several days (preferably 7) before they can move on to Step 2.²⁶¹

Step 2.
- Light aerobic exercise, keeping intensity between 50 and 70% of maximum heart rate for 20 minutes.²⁶⁶
  - Walking, swimming, stationary cycling

NOTE: It has been suggested in the literature that a rest period of seven days could help decrease the severity of symptoms related to the concussion and increase cognitive performance upon recovery.²⁶⁷ From Step 2 to 7, a minimum of 24 hours between steps is necessary.

Step 3
- Light aerobic exercise (50-70% Max Heart Rate for 20 minutes) and the addition of individual sport-specific drills
  - Specific drills should be incorporated to the workout and should not include any plyometrics and rotation/change of direction exercises such as spins, jumps.

Step 4
- Sport-specific exercise
  - Drills that are sport-specific, done individually or with a teammate. Increase duration of exercise, resistance training can be incorporated. Should not include head impact activities. Possible to incorporate plyometrics and rotation/change of direction exercises such as light jumps, spins.

Step 5
- Non-contact training drills
  - Practice more complex drills, increase resistance training, increase level of skills (jumps, spins)

Step 6
- Full practice with body contact

Step 7
- Return to play
  - Normal game play with body contact.

‡ Adapted from the Montreal Children’s Hospital Concussion Kit³⁵ & Zurich Consensus statement on concussion in sport.⁷
If a particular step during the graded RTP protocol was to cause symptoms, athletes should rest (cognitive and physical) and become symptom-free for a minimum of 24 hours before starting over at the previous step.
5.3 Return to Play for Adults (>25 years old)§

Although there is no current consensus on a stepwise approach to return to work following a mTBI, similar procedures to those of return to learn in children should be applied. In fact, before going back to physical activities, an adult should have succeeded in going back to work without experiencing symptoms. Hence, it is highly recommended that adults follow a similar return to work approach as the return to learn protocol for children, adolescents and young adults.

Step 1
• No Activity
  o Physical and cognitive rest to decrease symptoms
  NOTE: Adults should be symptom free for at least 24 hours before they can move on to Step 2

Step 2
• Light aerobic exercise, keeping intensity between 50 and 70% of maximum heart rate for 20 minutes. 66,68
  o Walking, swimming, stationary cycling
  NOTE: From Step 2 to 6, a minimum of 24 hours between steps is necessary

Step 3
• Light aerobic exercise (50-70% Heart Rate for 20 minutes) and addition of individual sport-specific drills
  o Specific drills should be incorporated to the workout and should not include any plyometrics and rotation/change of direction exercises such as spins, jumps.

Step 4
• Sport-specific exercise
  o Drills that are sport-specific, done individually or with a team-mate. Increase duration of exercise, resistance training can be incorporated. Should not include head impact activities. Possible to incorporate plyometrics and rotation/change of direction exercises such as light jumps, spins.

Step 5
• Non-contact training drills
  o Practice more complex drills, increase resistance training, increase level of skills (jumps, spins)

§ Adapted from the Zurich Consensus statement on concussion in sport. 7
Step 6
• Full practice with body contact

Step 7
• Return to play
  o Normal game play with body contact.

NOTE: If a particular step during the graded RTP protocol was to cause symptoms, athletes should rest (cognitive and physical) and become symptom-free for a minimum of 24 hours before starting over at the previous step.
Appendix 1 – SCAT3

Reproduced with permission

Appendix

What is the SCAT3?

The SCAT3 is a standardized tool for evaluating injured athletes for concussion and can be used in athletes aged from 13 years and older. It superseded the original SCAT and SCAT2 published in 2005 and 2009, respectively. For younger persons, ages 12 and under, please use the Child SCAT3. The SCAT3 is designed for use by medical professionals. If you are not qualified, please use the Sport Concussion Recognition Tool. Pre-season baseline testing with the SCAT3 can be helpful for interpreting post-injury test scores.

Specific instructions for use of the SCAT3 are provided on page 3. If you are not familiar with the SCAT3, please read through these instructions carefully. This tool may be freely copied in its current form for distribution to individuals, teams, groups and organizations. Any revision or any reproduction in a digital form requires approval by the Concussion in Sport Group.

NOTE: The diagnosis of a concussion is a clinical judgment, ideally made by a medical professional. The SCAT3 should not be used solely to make, or exclude, the diagnosis of concussion in the absence of clinical judgement. An athlete may have a concussion even if their SCAT3 is “normal”.

What is a concussion?

A concussion is a disturbance in brain function caused by a direct or indirect force to the head. It results in a variety of non-specific signs and/or symptoms (some examples listed below) and most often does not involve loss of consciousness. Concussion should be suspected in the presence of any one or more of the following:

- Symptoms (e.g., headache), or
- Physical signs (e.g., unsteadiness), or
- Impaired brain function (e.g., confusion) or
- Abnormal behaviour (e.g., change in personality).

Potential signs of concussion?

If any of the following signs are observed after a direct or indirect blow to the head, the athlete should stop participation, be evaluated by a medical professional and should not be permitted to return to sport the same day if a concussion is suspected.

Any loss of consciousness?  Y N

"If so, how long?":

- Balance or motor incoordination (stumble, slow / laboured movements, etc.)  Y N
- Orientation or confusion (unable to respond appropriately to questions)  Y N
- Loss of memory:
  - "If so, how long?":
    - Before or after the injury?  Y N

Visible facial injury in combination with any of the above:  Y N

Glasgow Coma Scale (E + V + M)

Potential spinal injury

Deteriorating mental status

Progressive, worsening symptoms or new neurologic signs

SIDELINE ASSESSMENT

Indications for Emergency Management

NOTE: A hit to the head can sometimes be associated with a more serious brain injury. Any of the following warrants consideration of activating emergency procedures and urgent transportation to the nearest hospital:

- Glasgow Coma score less than 15
- Deteriorating mental status
- Potential spinal injury
- Progressive, worsening symptoms or new neurologic signs

Maddocks Score

Maddocks score is validated for sideline diagnosis of concussion only and is not used for serial testing.

Any athlete with a suspected concussion should be removed from play, medically assessed, monitored for deterioration (i.e., should not be left alone) and should not drive a motor vehicle until cleared to do so by a medical professional. No athlete diagnosed with concussion should be returned to sports participation on the day of injury.
BACKGROUND

Name: __________ Date: __________

Concentration: Month in Reverse Order (1 pt. for entire sequence correct)

Concentration score ______ of 5

5 Neck Examination:

Range of motion: Tender and upper and lower limb sensation and strength

Findings:

6 Balance examination

Do one or both of the following tests:

Footwear (shoes, barefoot, braces, tape, etc.)

Modified Balance Error Scoring System (BESS) testing

Which foot was tested (i.e. which is the non-dominant foot)? ______
Testing surface (hard floor, field, etc.) ______

Condition

Double leg stance: ______
Single leg stance (non-dominant foot): ______
Tandem stance (non-dominant foot at back): ______

And/Or

Tandem gait: ______ Time (two of 4 trials): ______ seconds

7 Coordination examination

Upper limb coordination

Which arm was tested: ______

Coordination score ______ of 1

8 SAC Delayed Recall

Delayed recall score ______ of 5

SCAT3 sport concussion assessment tool | page 2

© 2013 Concussion in Sport Group

Scoring on the SCAT3 should not be used as a stand-alone method to diagnose concussion, measure recovery or make decisions about an athlete’s readiness to return to competition after concussion. Since signs and symptoms may evolve over time, it is important to consider repeat evaluation in the acute assessment of concussion.

37 CTSQ – April 2014
INSTRUCTIONS

Words in italics throughout the SCAT3 are the instructions given to the athlete by the tester.

Symptom Scale

“You should score yourself on the following symptoms, based on how you feel now”.

To be completed by the athlete. In situations where the symptom scale is being completed after exercise, it should still be done in a resting state, at least 10 minutes post-exercise.

For total number of symptoms, maximum possible is 12.

For symptom severity score, add all scores in table, maximum possible is 22/6 = 132.

SAC

1. Immediate Memory

“I am going to test your memory. I will read you a list of words and when I am done, repeat back as many words as you can remember, in any order.”

2 & 3. "I am going to repeat the same list again. Repeat back as many words as you can remember, in any order, even if you said the word before.”

Complete all 3 trials. Record score on trial 1 only. Read the words at a rate of one per second.

Score 1 pt. for each correct response. Total score equals sums across all 3 trials. Do not inform the athlete that delayed recall will be tested.

Concentration

Digits backward

“I am going to read you a string of numbers and when I am done, I am going to repeat them back to me backward. In reverse order of how I read them to you. For example, if I say 7-5-9, you would say 9-5-7. If correct, go to next string length. If incorrect, read trial 2. One point possible for each string length. Step after incorrect on both trials. The digits should be read at the rate of one per second.

Months in reverse order

“Now tell me the months of the year in reverse order. Start with the last month and go backwards. Do you say December, November . . . Go ahead!”

1 pt. for entire sequence correct.

Delayed Recall

The delayed recall should be performed after completion of the Balance and Coor.

“Do you remember that list of words I read a few times earlier? Tell me as many words from the list as you can remember in any order.”

Score 1 pt. for each correct response.

Balance Examination

Modified Balance Error Scoring System (BESS) testing

This balance testing is based on a modified version of the Balance Error Scoring System in SCAT3. A stopwatch or watch with a second hand is required for this testing.

“I am now going to test your balance. Please take your shoes off, roll up your pant legs above your ankles (if applicable), and remove any ankle taping (if applicable). This test will consist of three twenty-second tests with different stances.”

(a) Double leg stance:

“The first stance is standing with your feet together with your hands on your hips and with your eyes closed. You should try to maintain stability in that position for 20 seconds. I will be counting the number of times you move out of this position. I will start timing when you are set and have closed your eyes.”

(b) Single leg stance:

“If you were to look a bit, which foot would you use? This will be the dominant foot. Now stand on your non-dominant foot. The dominant leg should be held in approximately 10 degrees of hip flexion and 45 degrees of knee flexion. Again, you should try to maintain stability for 20 seconds with your hands on your hips and your eyes closed. I will be counting the number of times you move out of this position. If you stumble out of this position, open your eyes and return to the start position and continue balancing. I will start timing when you are set and have closed your eyes.”

(c) Tandem stance:

“Now stand heel-to-toe with your non-dominant foot in back. Your weight should be evenly distributed across both feet. Again, you should try to maintain stability for 20 seconds with your hands on your hips and your eyes closed. I will be counting the number of times you move out of this position. If you stumble out of this position, open your eyes and return to the start position and continue balancing. I will start timing when you are set and have closed your eyes.”

Balance testing – types of errors

1. Hands lifted offillac crest
2. Opening eyes
3. Step, stumble, or fall
4. Moving hip into >30 degrees abduction
5. Lifting forehead or heel
6. Remaining out of test position >5 sec

Each of the 20-second trials is scored by counting the errors, or deviations from the proper stance, accumulated by the athlete. The examiner will begin counting errors only after the individual has assumed the proper start position. The modified BESS is calculated by adding one error point for each error during the three 20-second tests. The maximum total number of errors for any single condition is 10. If the athlete commits multiple errors simultaneously, only one error is recorded but the athlete should quickly return to the testing position, and counting should resume once subject is set. Subjects that are unable to maintain the testing procedure for a minimum of five seconds at the start are assigned the highest possible score, ten, for that testing condition.

OPTION:

For further assessment, the same 3 stances can be performed on a surface of medium density foam (e.g., approximately 50/40 cm x 60 cm x 10 cm).

Random Gain

Participants are instructed to stand with their feet together behind a starting line (the test is best done with footwear removed). Then, they walk in a forward direction as quickly and as accurately as possible along a 38mm wide (sports tape), 3 meter line with an alternate foot heel-to-toe gait ensuring that they approximate their heel and toe on each step. Once they cross the end of the 3m-line, they turn 180 degrees and return to the starting point using the same gait. A total of 4 trials are done and the best time is recorded. Athletes should complete the test in 14 seconds. Athletes fail the test if they step off the line, have a separation between their heel and toe, or if they touch or grasp the examiner or an object. In this case, the time is not recorded and the trial repeated, if appropriate.

Coordination Examination

Upper Limb Coordination

Finger-to-nose (FTN) task

“I am going to test your coordination now. Please sit comfortably on the chair with your eyes open and your arm (either right or left) outstretched (shoulder flexed to 90 degrees and elbow and fingers extended), pointing in front of you. When I give a start signal, I would like you to perform the successive finger-to-nose repetitions using your index finger to touch the tip of the nose, and then return to the starting position, as quickly and as accurately as possible.”

Scoring: 5 correct repetitions in <4-seconds: =1
Note for testers: Athletes fail the test if they do not touch their nose, do not fully extend their elbow or do not perform five repetitions. Failure should be scored as 0.

References & Footnotes

1. This tool has been developed by a group of international experts at the 4th International Consensus meeting on Concussion in Sport held in Zurich, Switzerland in November 2012. The full details of the conference outcomes and the authors of the tool are published in The mBm Injury Prevention and Health Protection, 2012, Volume 47, Issue 5. The outcome paper will also be simultaneously co-published in other leading biomedical journals with the copyright held by the Concussion in Sport Group, to allow unrestricted distribution, providing no alterations are made.

Downloaded from bjsm.bmj.com on March 12, 2013 - Published by group.bmj.com
ATHLETE INFORMATION

Any athlete suspected of having a concussion should be removed from play, and then seek medical evaluation.

Signs to watch for
Problems could arise over the first 24–48 hours. The athlete should not be left alone and must go to a hospital at once if they:

- Have a headache that gets worse
- Are very drowsy or can’t be awakened
- Can’t recognize people or places
- Have repeated vomiting
- Behave unusually or seem confused, are very irritable
- Have seizures (arms and legs jerk uncontrollably)
- Have weak or numb arms or legs
- Are unsteady on their feet; have slurred speech

Remember, it is better to be safe.
Consult your doctor after a suspected concussion.

Return to play
Athletes should not be returned to play the same day of injury. When returning athletes to play, they should be medically cleared and then follow a stepwise supervised program, with stages of progression.

For example:

<table>
<thead>
<tr>
<th>Rehabilitation stage</th>
<th>Functional exercise at each stage</th>
<th>Objective of each stage</th>
</tr>
</thead>
<tbody>
<tr>
<td>No activity</td>
<td>Physical and cognitive rest</td>
<td>Recovery</td>
</tr>
<tr>
<td>Light aerobic exercise</td>
<td>Walking, running or stationary cycling, lifting light weights, no head impact activities</td>
<td>Increase heart rate</td>
</tr>
<tr>
<td>Sport-specific exercise</td>
<td>Walking &amp; light exercises, maintaining balance, no head impact activities</td>
<td>Add movement</td>
</tr>
<tr>
<td>Non-contact training</td>
<td>Progression to non-contact drills in football and ice hockey</td>
<td>Exercise coordination, and cognitive load</td>
</tr>
<tr>
<td>Full contact practice</td>
<td>Following medical clearance in contact training activities</td>
<td>Return to play</td>
</tr>
</tbody>
</table>

There should be at least 24 hours (or longer) for each stage and if symptoms recur the athlete should rest until they resolve once again and then resume the program at the previous asymptomatic stage. Resistance training should only be added in the later stages.

If the athlete is symptomatic for more than 10 days, then consultation by a medical practitioner who is expert in the management of concussion, is recommended.

Medical clearance should be given before return to play.

Notes:

CONCUSSION INJURY ADVICE

(To be given to the person monitoring the concussed athlete)

This patient has received an injury to the head. A careful medical examination has been carried out and no sign of any serious complications has been found. Recovery time is variable across individuals and the patient will need monitoring for a further period by a responsible adult. Your treating physician will provide guidance as to this timeframe.

If you notice any change in behaviour, vomiting, dizziness, worsening headache, double vision or excessive drowsiness, please contact your doctor or the nearest hospital emergency department immediately.

Other important points:
- Rest (physically and mentally), including training or playing sports until symptoms resolve and you are medically cleared
- No alcohol
- No prescription or non-prescription drugs without medical supervision.
  Specifically:
  - No sleeping tablets
  - Do not use aspirin, anti-inflammatory medication or sedating pain killers
  - Do not drive until medically cleared
  - Do not train or play sport until medically cleared

Appendix 2 – SCAT3 Child

Reproduced with permission

What is childSCAT3?
The Child-SCAT3 is a standardized tool for evaluating injured children for concussion and should be used in children aged from 5 to 12 years. It supersedes the original SCAT and the SCAT2 published in 2005 and 2009, respectively. For older persons, ages 13 years and over, please use the SCAT3. The Child-SCAT3 is designed for use by medical professionals. If you are not qualified, please use the Sport Concussion Recognition Tool Peresent baseline testing with the ChildSCAT3 can be helpful for interpreting post-injury test scores.

Specific instructions for use of the ChildSCAT3 are provided on page 3. If you are not familiar with the ChildSCAT3, please read through these instructions carefully. This tool may be freely copied in its current form for distribution to individuals, teams, groups and organizations. Any revision and any reproduction in a digital form require approval by the Concussion in Sport Group.

NOTE: The diagnosis of a concussion is a clinical judgment, ideally made by a medical professional. The ChildSCAT3 should not be used solely to make, or exclude, the diagnosis of concussion in the absence of clinical judgement. An athlete may have a concussion even if their ChildSCAT3 is “normal”.

What is a concussion?
A concussion is a disturbance in brain function caused by a direct or indirect force to the head. It results in a variety of non-specific signs and symptoms (like those listed below) and most often does not involve loss of consciousness. Concussion should be suspected in the presence of any one or more of the following:

- Symptoms (e.g., headache), or
- Typical signs (e.g., astereognosis), or
- Impaired brain function (e.g., confusion) or
- Abnormal behaviour (e.g., change in personality).

SIDELINE ASSESSMENT

Indications for Emergency Management

NOTE: A hit to the head can sometimes be associated with a more severe brain injury. If the concussed child displays any of the following, then do not proceed with the ChildSCAT3; instead activate emergency procedures and urgent transportation to the nearest hospital:

- Glasgow Coma score less than 15
- Deteriorating mental status
- Potential spinal injury
- Progressive, worsening symptoms or new neurologic signs
- Persistent vomiting
- Evidence of skull fracture
- History of Neurosurgery (e.g. Shunt)
- Persistent vomiting
- Deteriorating mental status
- Multiple injuries

Potential signs of concussion?
If any of the following signs are observed after a direct or indirect blow to the head, the child should stop participation, be evaluated by a medical professional and should not be permitted to return to sport the same day if a concussion is suspected.

Any loss of consciousness?

- “If so, how long?”

Balance or motor incoordination (stumbles, slow/laborious movements, etc.)?

- “If so, how long?”

Disorientation or confusion (ability to respond appropriately to questions)?

Loss of memory:

- “If so, how long?”

“Before or after the injury?”

Blank or vacant look:

Visible facial injury in combination with any of the above:

2

Sideline Assessment – child-Maddocks Score

“I am going to ask you a few questions, please listen carefully and give your best effort.”

Modified Maddocks questions (1 point for each correct answer)

Where were you at home?

0 1

Is it before or after lunch?

0 1

What did you have last lesson/class?

0 1

What is your teacher’s name?

0 1

child-Maddocks score

of 4

Any child with a suspected concussion should be REMOVED FROM PLAY, medically assessed and monitored for deterioration (i.e., should not be left alone). No child diagnosed with concussion should be returned to sports participation on the day of Injury.

BACKGROUND

Name:

Date/Time of Injury:

Examiner:

Date of Assessment:

Sport/Team/school:

Age:

Gender:

M F

Current school year/grade:

Dominant hand:

Mechanism of Injury (“tell me what happened”):

For Parent/carer to complete:

How many concussions has the child had in the past?

When was the most recent concussion?

How long was the recovery from the most recent concussion?

Has the child ever been hospitalized or had medical imaging done (CT or MRI) for a head injury?

Has the child ever been diagnosed with headaches or migraines?

Does the child have a learning disability, dyslexia, ADD/ADHD, seizure disorder?

Has the child ever been diagnosed with depression, anxiety or other psychiatric disorder?

Has anyone in the family ever been diagnosed with any of these problems?

Is the child on any medications? If yes, please list:

Glasgow coma scale (GCS)

Best eye response (E)

No eye opening

1

Eye opening in response to pain

2

Eye opening to speech

3

Eyes opening spontaneously

4

Best verbal response (V)

No verbal response

1

Incomprehensible sounds

2

Inappropriate words

3

Confused

4

Oriented

5

Best motor response (M)

No motor response

1

Extension to pain

2

Abnormal flexion to pain

3

Flexion/Withdrawal to pain

4

Localizes to pain

5

Obey commands

6

Glasgow Coma score (E + V + M)

of 15

GCS should be recorded for all athletes in case of subsequent deterioration.

Since signs and symptoms may evolve over time, it is important to consider repeat evaluation in the acute assessment of concussion.
INSTRUCTIONS

Words in italics throughout the Child-SCAT3 are the instructions given to the child by the tester.

Sideline Assessment – child-Maddocks Score

To be completed on the sideline in the playground, immediately following concussion. There is no requirement to repeat these questions at follow-up.

Symptom Scale

In situations where the symptom scale is being completed after exercise, it should still be done in a resting state, at least 10 minutes post exercise.

On the day of injury – the child is to complete the Child Report, according to how he/she feels now.

On all subsequent days – the child is to complete the Child Report, according to how he/she feels today and how he/she feels when

- the parent shows it to complete the Parent Report according to how the child has been over the previous 24 hours.

Standardized Assessment of Concussion – Child Version (SAC-C)

Orientation

Ask each question on the score sheet. A correct answer for each question scores 1 point. If the child does not understand the question, gives an incorrect answer, or no answer, then the score for that question is 0 points.

Immediate memory

“I am going to test your memory. I will read you a list of words, and when I am done, repeat back as many words as you can remember, in any order.”

Trials 2 & 3:

“Tandem gait”

Use a clock (with a second hand) or stopwatch to measure the time taken to complete this task.

Instruct the child to stand with their feet together (beginning on the test leg that was done with footwear removed). Then, they walk in a forward direction as quickly and as accurately as possible along a 3.6m wide (sports tape). Three trials with an alternate foot heel-to-toe gait ensuring that they approximate their heel and toe on each step. Once at the end of the line, the child moves 180 degrees and moves back to the starting point using the same gait. A total of 4 trials are done and the best time is retained. Children fail the test if they drop off the line, have a separation between their heel and toe, or if they touch or graze the examiner or an object. In this case, the time is not recorded and the trial repeated, if appropriate.

Explain to the child that you will time how long it takes them to walk to the end of the line and back.

Coordination examination

Upper limb coordination

The examiner should demonstrate the test to the child.

“I am going to test your coordination now. Please sit comfortably on the chair with your eyes open and your arm (either right or left) outstretched (shoulder level) 20 degrees above and fingers extended. When I give a start signal I would like you to perform five successive finger-to-nose repetitions using your index finger to touch the tip of the nose at a quick and as accurately as possible.”

Scoring: 5 correct repetitions in ≤ 4 seconds: 1

Note for tester: Children fail the test if they do not touch their nose, do not fully extend their elbow or do not perform five repetitions. Failure should be scored as 0.

References & Footnotes

1. This tool has been developed by a group of international experts at the 4th International Consensus meeting on Concussion in Sport held in Zurich, Switzerland in November 2008. The full details of the conference outcomes and the authors of the tool are published in: The British Journal of Sports Medicine. 2014; 48(3): 250-258.

Balance testing – types of errors - Parts (a) and (b)

1. Hands lifted off iliac crest

2. Opening eyes

3. Step, stumble, or fall

4. Moving hips into >30 degrees abduction

5. Ulling foot on heel or heel

6. Remaining out of position >5 sec

Each of the 20-second trials is scored by counting the errors, or deviations from the proper stance, accumulated by the child. The examiner will begin counting errors only after the child has assumed the proper start position. The modified BESS is calculated by adding one error point for each error during the two 20-second tests. The maximum total number of errors for any single condition is 10. If a child commits multiple errors simultaneously, only one error is recorded but the child should quickly return to the testing position, and counting should resume once subject is set. Children who are unable to maintain the testing procedure for a minimum of five seconds at the start are assigned the highest possible score, ten, for that testing condition.

OPTION: For further assessment, the same 2 stance can be performed on a surface of medium density foam (e.g., approximately 50cm x 40cm x 6cm).

Balance testing – types of error
CHILD ATHLETE INFORMATION

Any child suspected of having a concussion should be removed from play, and then seek medical evaluation. The child must NOT return to play or sport on the same day as the suspected concussion.

**Signs to watch for**

Problems could arise over the first 24–48 hours. The child should not be left alone and must go to a hospital at once if they develop any of the following:

- New Headache, or Headache gets worse
- Persistent or increasing neck pain
- Becomes drowsy or can't be woken up
- Can not recognise people or places
- Has Nausea or Vomiting
- Behaves unusually, seems confused, or is irritable
- Has any seizures (arms and/or legs jerk uncontrollably)
- Has weakness, numbness or tingling (arms, legs or face)
- Is unsteady walking or standing
- Has slurred speech
- Has difficulty understanding speech or directions

Remember, it is better to be safe than sorry.

**Always consult your doctor after a suspected concussion.**

**Return to school**

Concussion may impact on the child's cognitive ability to learn at school. This must be considered, and medical clearance is required before the child may return to school. It is reasonable for a child to miss a day or two of school after concussion, but extended absence is uncommon. In some children, a graduated return to school program will need to be developed for the child. The child will progress through the return to school program provided that there is no worsening of symptoms. If any particular activity worsens symptoms, the child will abstain from that activity until it no longer causes symptom worsening. Use of computers and internet should follow a similar graduated program, provided that it does not worsen symptoms. This program should include communication between the parents, teachers, and health professionals and will vary from child to child.

The return to school program should consider:

- Extra time to complete assignments/tests
- Quiet room to complete assignments/tests
- Avoidance of noisy areas such as cafeterias, assembly halls, sporting events, music class, drop class, etc
- Frequent breaks during class, homework, tests
- No more than one exam/day
- Shorter assignments
- Repetition/memory cues
- Use of peer helper/supervisor
- Reassurance from teachers that student will be supported through recovery through accommodations, workload reduction, alternate forms of testing
- Later start times, half days, only certain classes

Children must not be returned to play the same day of injury. When returning children to play, they should medically cleared and then follow a stepwise supervised program, with stages of progression.

**For example:**

<table>
<thead>
<tr>
<th>Rehabilitation stage</th>
<th>Functional exercise at each stage of rehabilitation</th>
<th>Objective of each stage</th>
</tr>
</thead>
<tbody>
<tr>
<td>No activity</td>
<td>Physical and cognitive rest</td>
<td>Recovery</td>
</tr>
<tr>

<td>Following medical clearance participate in normal training activities</td>
<td>Restore confidence and anxiety, functional skills by coaching staff</td>
</tr>
<tr>
<td>Return to play</td>
<td>Normal game play</td>
<td></td>
</tr>
</tbody>
</table>

Children should be monitored for at least 10 days, and reviewed by a health practitioner before return to play. If there are any doubts, management should be referred to a qualified health practitioner, expert in the management of concussion in children.

**Return to sport**

There should be no return to play until the child has successfully returned to school/learning, without worsening of symptoms. Children must not be returned to play the same day of injury. When returning children to play, they should medically cleared and then follow a stepwise supervised program, with stages of progression.

**Notes:**

---

CONCUSSION INJURY ADVICE FOR THE CHILD AND PARENTS / CARERS

(To be given to the person monitoring the concussed child)

This child has received an injury to the head. A careful medical examination has been carried out and no sign of any serious complications has been found. It is expected that recovery will be rapid, but the child will need monitoring for the next 24 hours by a responsible adult.

If you notice any change in behavior, vomiting, dizziness, worsening headache, double vision or excessive drowsiness, please call an ambulance to transport the child to hospital immediately.

**Other important points:**

- Following concussion, the child should rest for at least 24 hours.
- The child should avoid any computer, internet or electronic gaming activity if these activities make symptoms worse.
- The child should not be given any medications, including pain killers, unless prescribed by a medical practitioner.
- The child must not return to school until medically cleared.
- The child must not return to sport or play until medically cleared.

<td></td>
<td></td>
</tr>
</tbody>
</table>

**NOTE:** The GSC should be used not only for the initial evaluation, but also for each subsequent follow-up assessment until signs and symptoms have cleared at rest and during physical exertion. In lieu of simply checking each symptom present, the CAT(C) Certification Candidate can ask the athlete to grade or score the severity of the symptom on a scale of 0-6 where 0 = not present. 1 = mild. 2 = moderate and 6 = most severe.

After a head injury or accident some people experience symptoms that can cause worry or nuisance. We would like to know if you now suffer any of the symptoms given below. Because many of these symptoms occur normally, we would like you to compare yourself now with before the accident. For each symptom listed below please circle the number that most closely represents your answer.

0 = not experienced at all
1 = no more of a problem
2 = a mild problem
3 = a moderate problem
4 = a severe problem

Compared with before the accident, do you now (i.e., over the last 24 hours) suffer from:

Appendix 6 – Rivermead Post Concussion Symptoms Questionnaire (cont.)

Rivermead Post Concussion Symptoms Questionnaire (cont.)
Modified (Rpq-3 And Rpq-13)² Printed With Permission: Modified Scoring System From Eyres 2005 ²⁶

Administration only

Individual item scores reflect the presence and severity of post concussive symptoms. Post concussive symptoms, as measured by the RPQ, may arise for different reasons subsequent to (although not necessarily directly because of) a traumatic brain injury. The symptoms overlap with broader conditions, such as pain, fatigue and mental health conditions such as depression²⁷.

The questionnaire can be repeated to monitor a patient’s progress over time. There may be changes in the severity of symptoms, or the range of symptoms. Typical recovery is reflected in a reduction of symptoms and their severity within three months.

Scoring

The scoring system has been modified from Eyres, 2005²⁶.

The items are scored in two groups. The first group (RPQ-3) consists of the first three items (headaches, feelings of dizziness and nausea) and the second group (RPQ-13) comprises the next 13 items. The total score for RPQ-3 items is potentially 0–12 and is associated with early symptom clusters of post concussive symptoms. If there is a higher score on the RPQ-3, earlier reassessment and closer monitoring is recommended.

The RPQ-13 score is potentially 0–62, where higher scores reflect greater severity of post concussive symptoms. The RPQ-13 items are associated with a later cluster of symptoms, although the RPQ-3 symptoms of headaches, dizziness and nausea may also be present. The later cluster of symptoms is associated with having a greater impact on participation, psychosocial functioning and lifestyle. Symptoms are likely to resolve within three months. A gradual resumption of usual activities is recommended during this period, appropriate to symptoms. If the symptoms do not resolve within three months, consideration of referral for specialist assessment or treatment services is recommended.

Appendix 7 – Post-Concussion Symptom Inventory (PCSI)

Reproduced with permission

PCSI Administration Manual

The Post-Concussion Symptom Inventory (PCSI) was developed to assess common post-concussion physical, cognitive, and behavioral/emotional symptoms directly via the child’s self-report. Age-specific PCSI forms were created appropriate to the age/developmental level of the child (i.e., age 5-7 years, 8-12 years and 13-18 years). A companion parent symptom report form was also developed which serves to augment symptom assessment in children by gathering parent-observed symptoms (Gioia et al., 2009).

Forms. The PCSI for the 5 to 7 year age group is comprised of 5 symptom rating items, removing items with complex vocabulary (e.g., fogginess, nausea, irritability), subtle internal states (e.g., fogginess), and other items not likely monitored by younger children (e.g., sleep). The PCSI for 5- to 7-year-olds includes five items that tap physical (three items), cognitive (one item), and emotional (one item) symptoms.

The PCSI form for 8- to 12-year-olds includes 17 items that assess physical (eight items), cognitive (four items), emotional (three items), and fatigue (two items) symptoms.

The PCSI for the 13- to 18-year olds includes 21 items that assess physical (eight items), cognitive (six items), emotional (four items) and fatigue (three items) symptoms.

The Parent PCSI is composed of 20 items that assesses physical (eight items), cognitive (five items), emotional (four items) and fatigue (three items) symptoms.

Each of the post-injury forms includes an additional item asking the child/adolescent/parent to indicate if they are “acting differently than before the injury.” This item is presented as a general summary judgment of their overall state.

Administration. One may use the PCSI to collect symptom report data as a pre-injury baseline, retrospective baseline and a post-injury measurement. It is important to understand the different time frames of the symptom reporting and the corresponding differences in administration. When administering the PCSI as a Pre-Injury Baseline or Post-Injury assessment, each symptom is preceded by the phrase “Yesterday or Today” to give the child the time frame within which they should be making their decision about the symptom’s presence and degree. The PCSI is intended to assess the child’s current symptom state and not whether the child has ever experienced the symptom. This is a very important point that examiners must emphasize to the child and parent – we want to know how the child is currently feeling. The same intent and emphasis applies whether the child is taking a baseline or post-injury exam.

When administering the PCSI post-injury, it is often useful to find out how the child normally feels, this is known as a Retrospective Baseline. In this case, the child is asked to report if they experienced any of the symptoms prior to the injury (and if so, to what degree).

Scores. The PCSI scales produce a Total Symptom score for the 5-7 year, 8-12 year, 13-18 year and Parent PCSI versions, as well as scores reflecting the specific Physical, Cognitive, Emotional, and Fatigue symptom domains for 8-12, 13-18 and Parent Versions. Scores for the PCSI are simple sums of the number and degree of symptoms.

Child Report Form Age 13-18 (PCSI)  

Post-Concussion Symptom Inventory (PCSI)  
Self-Report Assessment Form  
Pre and Post-Injury Report  
Ages 13-18

Patient Name: ___________________________  Today’s date: ____________  
Birthdate: ___________________  Age: ____________

**Instructions:** We would like to know if you have had any of these symptoms before your injury. Next, we would like to know if these symptoms have changed after your injury. Please rate the symptom at two points in time—Before the Injury/Pre-Injury and Currently.

Please answer all the items the best that you can. Do not skip any items. Circle the number to tell us how much of a problem this symptom has been for you.

0 = Not a problem  3 = Moderate problem  6 = Severe problem

RETURN TO SPORTS FOLLOWING A CONCUSSION

If you have sustained a concussion, this action plan is recommended before you put your team jersey back on for the game.

You must complete your recommended period of rest and follow the activity restrictions. You should be symptom-free at rest for a full week before returning to any physical activity. When you are ready to return to play follow these gradual progressive steps.

There should be approximately 24 hours in between each step. If any symptoms return at any time during this action plan, stop working out. Rest until you are symptom-free for 24 hours. Then return to the previous step. If symptoms do not resolve or get worse, you are urged to seek medical attention.

★ STEP 1: Light general conditioning exercises
• NO CONTACT.
• Begin with a warm up (stretching/flexibility) for 5-10 minutes.
• Start a cardio workout of 15-20 minutes which can include: stationary bicycle, treadmill, fast paced walking, light jog, rowing or swimming.

★ STEP 2: General conditioning and sport specific skill work done individually
• NO CONTACT.
• Begin with a warm up (stretching/flexibility) for 5-10 minutes.
• Increase intensity and duration of cardio workout to 20-30 minutes.
• Begin sport specific skill work within the workout, but no spins, dives or jumps.

★ STEP 3: General conditioning, skill work done individually and with a team-mate
• NO CONTACT.
• Increase duration of session to 60 minutes. Begin resistance training.
• Continue practicing sport specific individual skills.
• May begin general shooting, kicking or passing drills with a partner.
• May start beginner level spins, dives and jumps.

★ STEP 4: General conditioning, skill work and team drills
• NO CONTACT. NO SCRIMMAGES.
• Resume pre-injury duration of practice and team drills.
• Increase resistance training and skill work as required.
• Gradually increase skill level of spins, dives and jumps.

★ STEP 5: Full practice with body contact
• CONTACT. SCRIMMAGES.
• Participate in a full practice to get yourself back in the lineup. If completed with no symptoms, discuss with the coach about getting back in the game.
• Coaches must make sure that the athlete has regained his/her pre-injury skill-level and is confident in his/her ability to return to activity.

★ STEP 6: Return to competition
